

AZURE APP SERVICE

Azure App Service feature that provides a fully isolated and dedicated environment for running App Service apps securely at high scale. It is a Platform as a Service (PaaS) offering from Microsoft that simplifies building, deploying, and scaling web applications, APIs, and mobile backends. It allows developers to focus on their code rather than managing infrastructure, including servers, networks, and storage. App Service supports various languages and frameworks, making it versatile for different projects.

Types of App Services:

*.Web Apps:

It provides a way to host web applications without needing to manage the underlying infrastructure. It allows developers to focus on building applications rather than managing servers, operating systems, or web servers. Azure Web Apps supports various programming languages and frameworks, including .NET, Java, Node.js, Python, and PHP.

*.API Apps:

API apps are offering of App Service that helps to host Web APIs. This enables us to expose existing or new APIs. This is also a part of the platform as a service and we don't need to worry about infrastructure plumbing to bring our APIs up and running.

*.Logic Apps:

Logic apps enable us to create functional workflows by orchestrating software as a service component. These are basically used to connect different components of a solution to manage and trigger events and perform the desired action on some other service.

*.MobileApps:

Mobile Apps enable us to build a backend for Mobile applications. It can provide capabilities to mobile client applications. This can be considered to be the same as a web service to support mobile client scenarios. The client can be Windows Universal apps, IOS apps, windows apps etc..

*.Function Apps:

Function Apps are serverless, event-driven computing services that allow you to run code in the cloud without managing infrastructure. They enable you to write code that responds to specific events, such as HTTP requests, queue messages, or changes in data sources, according to Microsoft Azure.

App Service Environment:

App Service Plan:

An App Service plan defines the compute resources (like CPU, memory, and storage) that your web app or API app will use.

Limitations:

*. No Remote Desktop Connection—Since app services are part of the broader platform as a service modal, we have very limited access to the infrastructure on which they run. This makes it difficult to troubleshoot issues related to performance as we cannot log into the server and see log files or event viewer.

*. No support for third-party Software management tools- Since we do not have to manage the server at all, we have no authority to install any monitoring tools like Dynatrace or Splunk.

*. Performance Counters not visible- In order to keep the healthy state of an application, we always tend to see the performance indexes on key workloads like IIS queues but with app service in Azure, this is still not available.
